

Alert-to-Case Lifecycle

MISP -> TheHive -> Analyst -> Closure

Stage 1 — MISP — Threat Intelligence Recorded

An analyst creates an Event in MISP documenting a threat (e.g., a ransomware campaign), adding Attributes (C2 IPs, file hashes, mutex) and a TLP tag (TLP:AMBER). The event is published.

Stage 2 — TheHive — Automatic Alert Import

TheHive's MISP connector polls the MISP server on a set interval. Because the event is published and within the connector's age/organisation filters, TheHive creates a corresponding Alert, carrying over the title, severity, TLP tag, and all observables automatically.

Stage 3 — Analyst — Triage the Alert

An analyst reviews the new alert in TheHive's Alert queue, assigns themselves, and decides it represents a genuine incident worth formal investigation rather than a false positive.

Stage 4 — Promote to Case

The analyst clicks New case from alert, converting the alert into a full Case. All observables and tags carry over automatically, giving the analyst a structured workspace to investigate.

Stage 5 — Investigation — Tasks Assigned

The analyst adds specific tasks to the case (e.g., Enrich IOCs, Isolate endpoint, Notify stakeholders) and assigns each to the responsible person, tracking progress as each is completed.

Stage 6 — Enrichment

As part of the Enrich IOCs task, the analyst runs an enrichment tool (e.g., ioc_enricher.py) against the case's observables, checking sources like VirusTotal, AbuseIPDB, and OTX, and attaches the output to the case as supporting evidence.

Stage 7 — Closure

Once all tasks are completed and the incident is resolved (e.g., endpoint isolated, stakeholders notified), the analyst closes the case, with a full, auditable record of the alert's origin, the investigation steps taken, and the evidence gathered.

This end-to-end flow — threat intelligence recorded in MISP, automatically surfaced as an alert in TheHive, triaged and promoted into a formally-tracked case with assigned tasks and attached evidence — is the standard workflow a SOC analyst follows when handling an active incident in a mature MSSP environment.
